

The Hierarchy of Evidence

The Hierarchy of evidence is based on summaries from the National Health and Medical Research Council (2009), the Oxford Centre for Evidence-based Medicine Levels of Evidence (2011) and Melynyk and Fineout-Overholt (2011).

- I Evidence obtained from a systematic review of all relevant randomised control trials.
- II Evidence obtained from at least one well designed randomised control trial.
- III Evidence obtained from well-designed controlled trials without randomisation.
- IV Evidence obtained from well designed cohort studies, case control studies, interrupted time series with a control group, historically controlled studies, interrupted time series without a control group or with case- series
- V Evidence obtained from systematic reviews of descriptive and qualitative studies
- VI Evidence obtained from single descriptive and qualitative studies
- VII Expert opinion from clinicians, authorities and/or reports of expert committees or based on physiology

Replogle Tube Management

Please note: minimal literature & evidence available on Replogle tube management.

All evidence level VII.

Further research required into this area.

Alberti D, Boroni G, Corasaniti L & Torri F. 2011. "Esophageal atresia: pre and post-operative management." <i>Journal of Maternal-Fetal and Neonatal Medicine</i> . 24 (S(1): 4-6.	VII	"A 10F Replogle tube is placed in the upper esophagus and placed in continuous suction; the double-lumen Replogle tube allows the aspiration of secretions, but limits the suction on the mucosa preventing ulcerations. Quite frequently the suction catheter becomes blocked by thick salivary secretions with a significant risk of aspiration if not recognized. Frequent irrigations with saline or infusion of 3–5cc of air are useful to prevent blockage of the Replogle tube; sometimes the tube must be replaced."
Bairdain, S., Hamilton, T.E., Smithers, C.J., Manfredi, M., Ngo, P., & Gallagher, D., Zurakowski, D., Foker, J.E., & Jennings, R.W. (2015). Foker process for the correction of long gap esophageal atresia: Primary treatment versus secondary treatment after prior esophageal surgery. <i>Journal of Pediatric Surgery</i> , 50(6): 933-937. doi: 10.1016/j.jpedsurg.2015.03.010	IV	"The Foker process (FP) uses tension-induced growth for primary esophageal reconstruction in patients with long gap esophageal atresia."
Braithwaite, I. (2011). Continuous low suction pressure: an innovative solution to transporting patients with Replogle tubes. <i>Infant</i> , 7(4):132-133.	VII	"Replogle suggested that his design of a double lumen catheter should be used with suction pressures of -25-30mmHg, which equates to 3-4kPa or 34-40cmH2O of negative pressure."

<p>Cardinal Health (2020). Argyle™ Replogle Suction Catheters. Accessed June 22, 2020, https://www.cardinalhealth.com.au/en_au/medical-products/patient-care/obstetric-and-neonatal/neonatal-care/argyle-replogle-suction-catheters.html</p>	VII	<p>Product description:“ARGYLE™ replogle suction catheters were specially designed for the neonate. Our replogle catheters are latex-free and are available in 6 Fr, 8 Fr and 10 Fr sizes. They feature a clear double-lumen tube, three smooth eyes and are highly X-Ray opaque. Venting action provides safe, effective drainage. The replogles are marked from 5cm to 25cm for measuring the depth of insertion.”</p>

VII

Recommendations:
"Insertion Precautions:
Some medical and surgical conditions warrant special consideration before Replogle® suction catheter placement. The physician weighs the risks and benefits of Replogle® suction catheter placement for patients with these conditions. In these instances placement of Replogle® suction catheters may be restricted to physician or advanced practice nurse.

- Esophageal atresia with fistula between upper esophageal pouch and trachea.
- Growth induction sutures on proximal pouch.
- Esophageal leak.'

'...Maintain low continuous wall suction of Replogle® suction catheters at 20-40mmHg. Assess Replogle® suction catheter a minimum of hourly for correct insertion depth and patency.
Gently irrigate the blue "vent" port of the Replogle® suction catheter with 1-2 ml air of normal saline every 2-4 hours as indicated.....
Patients with an unrepaired fistula between the upper oesophageal pouch and trachea have Replogle® suction catheter flushed with air only.
If the catheter not patent attempt the following:

- a. Gently flush blue "vent" port with 1-2 ml air.
- b. If not patent, gently flush blue "vent" port with 1-2ml normal saline. Saline is preferred over water in case of inadvertent tracheal aspiration.
- c. If still not patent, replace Replogle® suction catheter."

<p>Hawley, A. 2001. Long-gap Oesophageal Atresia – A Nursing Perspective. <i>Journal of Child Health Care</i>. 5 (1). Pp.19-25.</p>	VII	<p>Discussion included:</p> <p>“Problems identified with Replogle tubes:</p> <ul style="list-style-type: none">• Difficulty with correct placement• Tubes moving out of the correct position• Trauma to the oesophageal pouch from continuous suction or misplaced tube.• Blockage with possible aspiration• Difficulty with size 10fg Replogle tubes in premature infants (due to the large diameter of the tube).”

Hawley, AD & Harrison D. 'Suctioning Practices for the upper oesophageal pouch in infants with unrepaired oesophageal atresia in Australia and New Zealand.' P105. *Perinatal Society of Australia and New Zealand Annual Congress* March 2003, Hobart, Australia.

VI

Findings:

"A Replogle tube was used in 61% of the NICUs surveyed. A Replogle tube is double lumen tube; one lumen is for drainage of saliva and the other functions as an air vent. The Replogle tube is connected to continuous low pressure suction to aspirate saliva from the upper oesophageal pouch."

"Intermittent suctioning of the upper oesophageal pouch was used in 15% of NICUs. 23% of NICUs used a combination of intermittent and Replogle suction."

"There are varied practices throughout Australian and New Zealand NICUs with regards to suctioning of the upper oesophageal pouch in infants with unrepaired oesophageal atresia."

"There is no evidence available in the literature outlining which method results in the best outcomes (short and long term) to infants and children with this condition."

"Further research needs to be undertaken to establish the most appropriate method for providing suction of the proximal oesophageal pouch."

<p>Jawaheer G & Hocking M. 2009. 'Initial management of an infant with oesophageal atresia' Southern West Midlands Newborn Network.</p>	<p>VII</p>	<p>"The Replogle tube should be connected to low level suction with the pressure set at 5Kpa and increased as required to ensure continuous flow of secretions from the upper oesophagus (up to a maximum of 10Kpa). Patency of the Replogle tube should be checked every 15 minutes and the tube should be flushed via the blue side arm with 0.5ml saline if there is no movement of secretions."</p>

Collect specimens of oral secretions as requested."</p> <p>"Do not include instilled volumes of sodium chloride 0.9% within fluid balance. Sodium chloride 0.9% instilled is continuously aspirated and therefore not an intake."</p>

<p>Leung, T.S.M., & Bayston, R., & Spitz, L. (1985). Bacterial colonisation of the upper pouch in neonates with oesophageal atresia. <i>Z Kinderchirurgie</i>, 41: 78-80. DOI: 10.1055/s-2008-1043314</p>	<p>VI</p>	<p>Described research study “the bacterial flora in the upper oesophageal pouch of forty neonates with oesophageal atresia was studied at daily intervals preoperatively. Of the twenty-nine infants whose oesophagus was anastomosed within 24 hours of admission, no organisms were isolated in sixteen, despite the fact that only nine of these patients had antibiotics. The remaining thirteen grew oropharyngeal organisms. Of eleven infants having delayed anastomosis eight received antibiotics. All eleven grew organisms in the upper pouch. Pseudomonas and serratia grew only in those receiving antibiotics. These results suggest that prophylactic antibiotics are rarely indicated. Efficient continuous aspiration of the pouch is probably more important.”</p>
